- Inverse modeling technique
- Posterior Evaluation
- Results
- Conclusion

# Introduction

## Ammonia

The need to sustain food production, because of growing populations, causes the increased agricultural emissions of  $\text{NH}_3$  with perturbations of:

- Nitrogen cycle and biogeochemical process
- Inorganic Fine Particulate Matter (PM)
- Climate change

Source: Wikipedia

# Introduction

## Nitrogen cycle and biogeochemical process

- Acidification of terrestrial ecosystems
- Loss of biodiversity

Bernhard, A. (2010) The Nitrogen Cycle: Processes, Players, and Human Impact. *Nature Education Knowledge* 3(10):25

# Introduction

## Inorganic Fine Particulate Matter (PM)

- A significant role in the formation of inorganic fine aerosols
- Ammonia neutralizes sulfate and nitrate.
  - leading to various health issues such as cardiovascular disease, asthma, and respiratory problems (Cheng & Wang-Li, 2019; Pui et al., 2014)

Source: Holt et al, 2015

# Introduction

## Climate Change (Radiative Forcing)

- Ammonia can be converted to Aerosols which have two effects upon climate:
  1. They can directly reflect sunlight back away from the Earth.
  2. They can interact with clouds

# Introduction

5

## Uncertainty in Ammonia Emissions

(Unit: Teragram N per year)

| Source                  | Global | North America | Contiguous US | China |
|-------------------------|--------|---------------|---------------|-------|
| Schlesinger and Hartley | 75     |               |               |       |
| Dentener and Crutzen    | 45     | 5.2           |               |       |
| Bouwman et al.          | 54     | 3.6           |               |       |
| EDGAR v4.2              | 40.6   | 4.1           | 2.9           |       |
| Moss et al.             | 38.5   | 5.1           | 3.4           |       |

- **This uncertainty would be propagated in estimation of PM and nitrogen cycle.**

# Introduction

## Reduction in Uncertainty in Ammonia Emissions

- Inverse modeling methods:
  - A well-established approach for refining emission inventories and constraining modeling predictions.
- Observation:
  - Remote sensing data, such as  $\text{NH}_3$  columns from Cross-track Infrared Sounder (CrIS) instrument, are commonly employed for inverse modeling techniques.

# Introduction

7

- Remote sensing data:
  - Advantage: Contribute to our understanding of pollutant spatial patterns.
  - Limitations: inadequate spatial and temporal coverage and uncertainties in measurements.
- In contrast, chemical transport models (CTM):
  - Advantage: comprehensive data with high spatiotemporal resolution for all species.
  - Limitations: uncertainties arising from the numerical representation of chemical and physical processes in the atmosphere, as well as uncertainties in modeling inputs.
- By combining the strengths of modeling data and observations, inverse modeling techniques enhance modeling predictions by effectively addressing uncertainties present in both the predictions and observational data.

# Tasks

- Task 1: Preparation of comprehensive satellite, in situ, and modeling data for iFDMB method,
- Task 2: Development of the Reduced-Complexity CMAQ Model (RCCM) for  $\text{NH}_3$  and refinement of  $\text{NH}_3$  emissions using iterative Finite Difference Mass Balance (iFDMB) with the combination of CMAQ model and IASI/CrIS satellite observations,
- Task 3: Investigation of  $\text{PM}_{2.5}$  concentrations using the updated emission inventory.

# Modeling Setup

- Weather Research and Forecasting (WRF):
  - Version 4.2
  - Domain sizes of 150×150 for the 12-km
  - The initial and boundary conditions from the North American Mesoscale Forecast System (NAM) reanalysis datasets.
- Sparse Matrix Operator Kernel Emissions (SMOKE)
  - Emissions input from National Emissions Inventory (NEI)
  - NEI point sources, NEI nonpoint sources, NEI on-road sources, and NEI nonroad sources.
  - Biogenic Emissions from the Biogenic Emissions Inventory System (BEIS3)
  - NEI 2017 employed to produce emissions for Texas throughout the entire year of 2019
  - Biogenic oceanic emissions for the Gulf of Mexico from the Emissions Database for Global Atmospheric Research (EDGAR)
- Community Multiscale Air Quality (CMAQ):
  - Chemical transport model developed and maintained by the US EPA
  - Version 5.0.1

# Inverse Modeling Setup

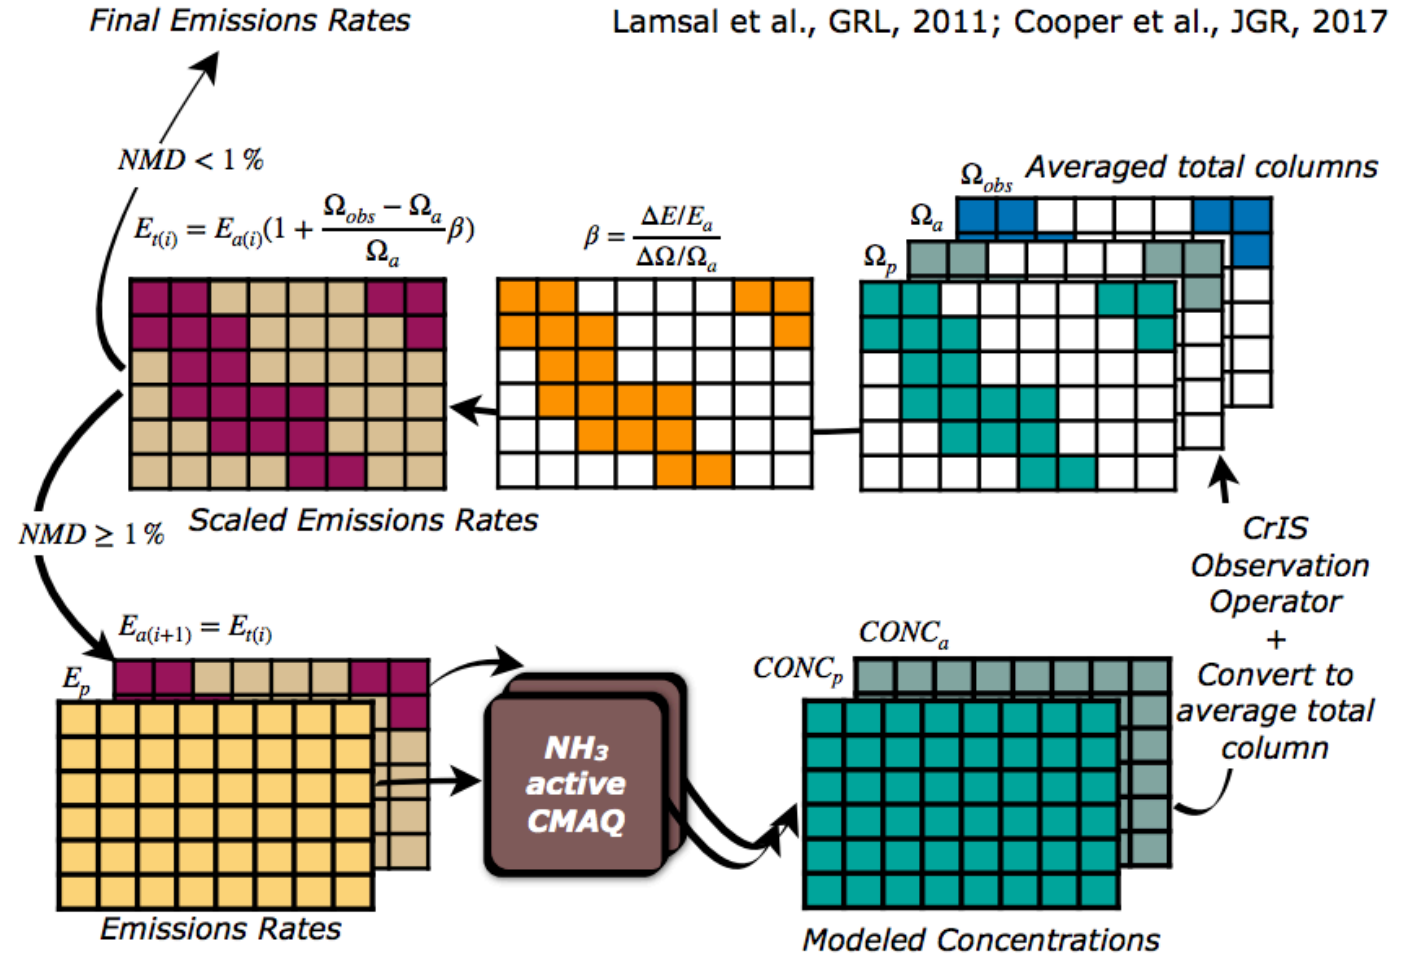

10

- Inverse modeling technique: iFDMB

$$E_t = E_a \left( 1 + \frac{1}{\beta} \frac{\Omega_o - \Omega_a}{\Omega_a} \right)$$

$$\beta = \frac{\Delta\Omega/\Omega}{\Delta E/E}$$

- $\beta$  is the initial sensitivity by a simulation with  $E_a$  perturbed by %20
- the normalized mean difference (NMD) of 2% is has been employed

# Inverse Modeling Setup

11

- Satellite data
  - $\text{NH}_3$  column density data for the year 2019 from:
    - Cross-track Infrared Sounder (CrIS)
    - Infrared Atmospheric Sounding Interferometer (IASI)

- Observation operator
  - For an apple-to-apple comparison with satellite column density, the vertical column of the model should be calculated:

$$VCD_i = -c_i \times \Delta P_i \times 2.119 \times 10^{14}$$

$$VCD = \sum_i VCD_i$$

# Inverse Modeling Setup

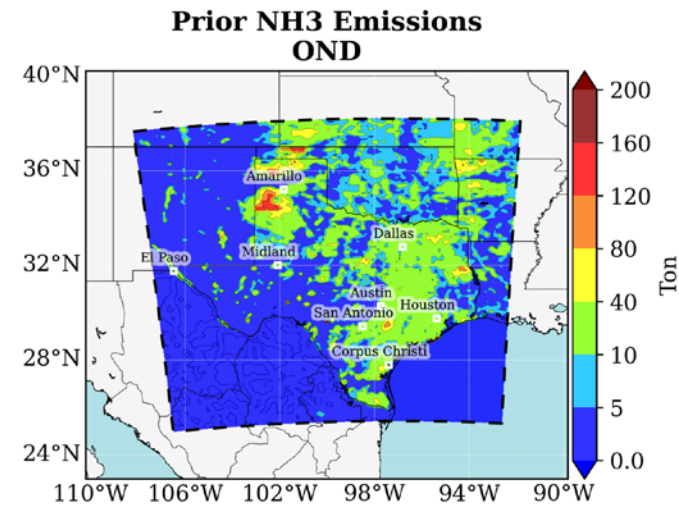

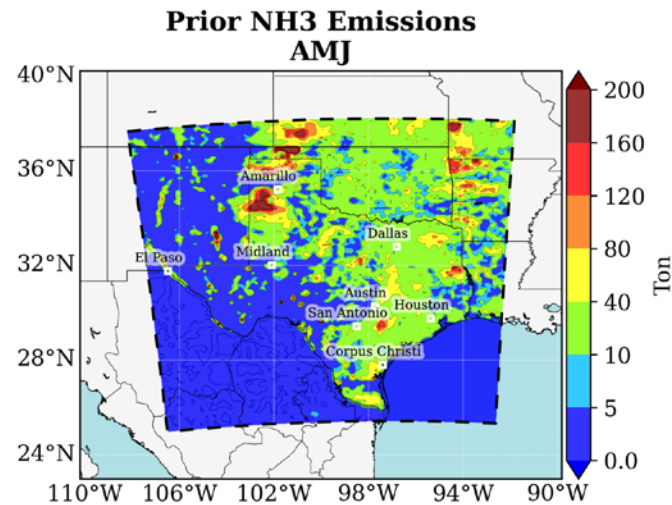

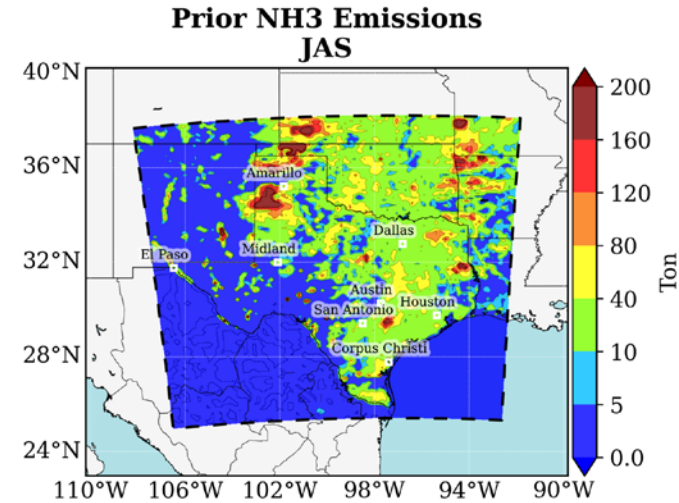

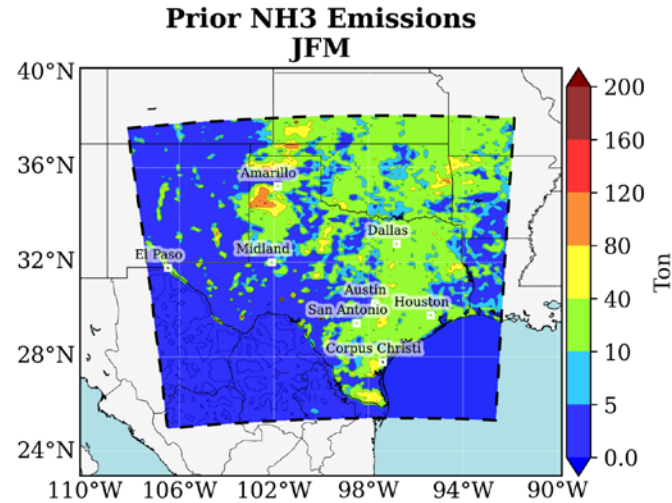

12

- Reduced-Complexity CMAQ Model (RCCM) for  $\text{NH}_3$ 
  - iFDMB is computationally expensive and requires numerous iterations
  - To reduce the computational cost, an RCCM was employed to simulate  $\text{NH}_3$
  - $\text{NH}_3$  and  $\text{NH}_4^+$  are considered as two tracer pollutants of the model
  - All of the chemical processes of other species are turned off
  - Include dry and wet deposition, the transport of  $\text{NH}_3$  and  $\text{NH}_4^+$ , and  $\text{NH}_x$  partitioning
  - ISORROPIA-II in the aerosol module calculates the gas-particle partitioning of  $\text{NH}_3$  and  $\text{NH}_4^+$
  - To handle the chemical processes, offline files required for running RCCM
  - Offline files contain sulfate ( $\text{SO}_4^{2-}$ ), nitric acid ( $\text{HNO}_3$ ), nitrate ( $\text{NO}_3^-$ ), chloride (Cl), sodium (Na), hydrochloric acid (HCl) concentration in all times steps

# Inverse Modeling Setup

13

- A-priori  $\text{NH}_3$  Emissions over the domain

# Posterior evaluation

14

- In order to assess the efficiency of the model:
  - Comparison between the posterior and prior estimates versus data from the CrIS/IASI satellites.
- The evaluation of the posterior emissions:
  - Comparison between the posterior simulation from updated emissions with surface measurements
  - For  $\text{NH}_3$  concentration:
    - The Ammonia Monitoring Network (AMoN) from the National Atmospheric Deposition Program (NADP).
    - Biweekly  $\text{NH}_3$  concentration
  - For  $\text{NH}_4^+$  wet deposition:
    - The NADP's National Trends Network (NTN)
    - Weekly wet deposition

## Adjusted emissions

- Across all quartiles and annual updated emissions, a noticeable increase in ammonia emission levels is observed over Texas.
- The coastline and extending over the Gulf of Mexico, demonstrates significantly elevated emission levels in comparison to the a-priori emissions.
- The updated emissions derived through our inverse modeling suggest the necessity of a thorough reevaluation of ammonia emissions from the Gulf of Mexico.

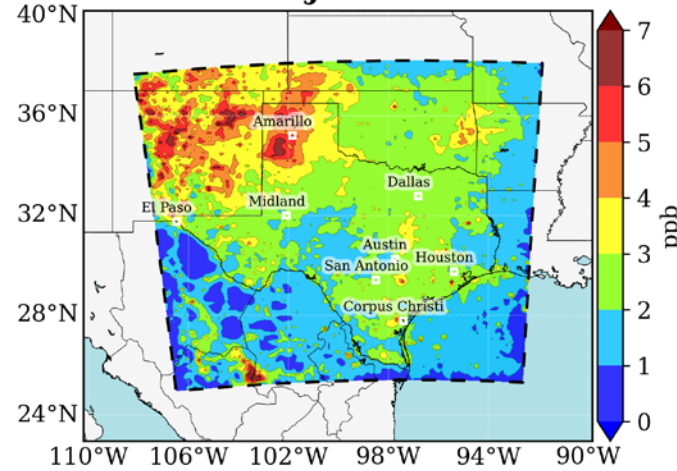

# Results

## Posterior NH<sub>3</sub> concentrations

# Results

23

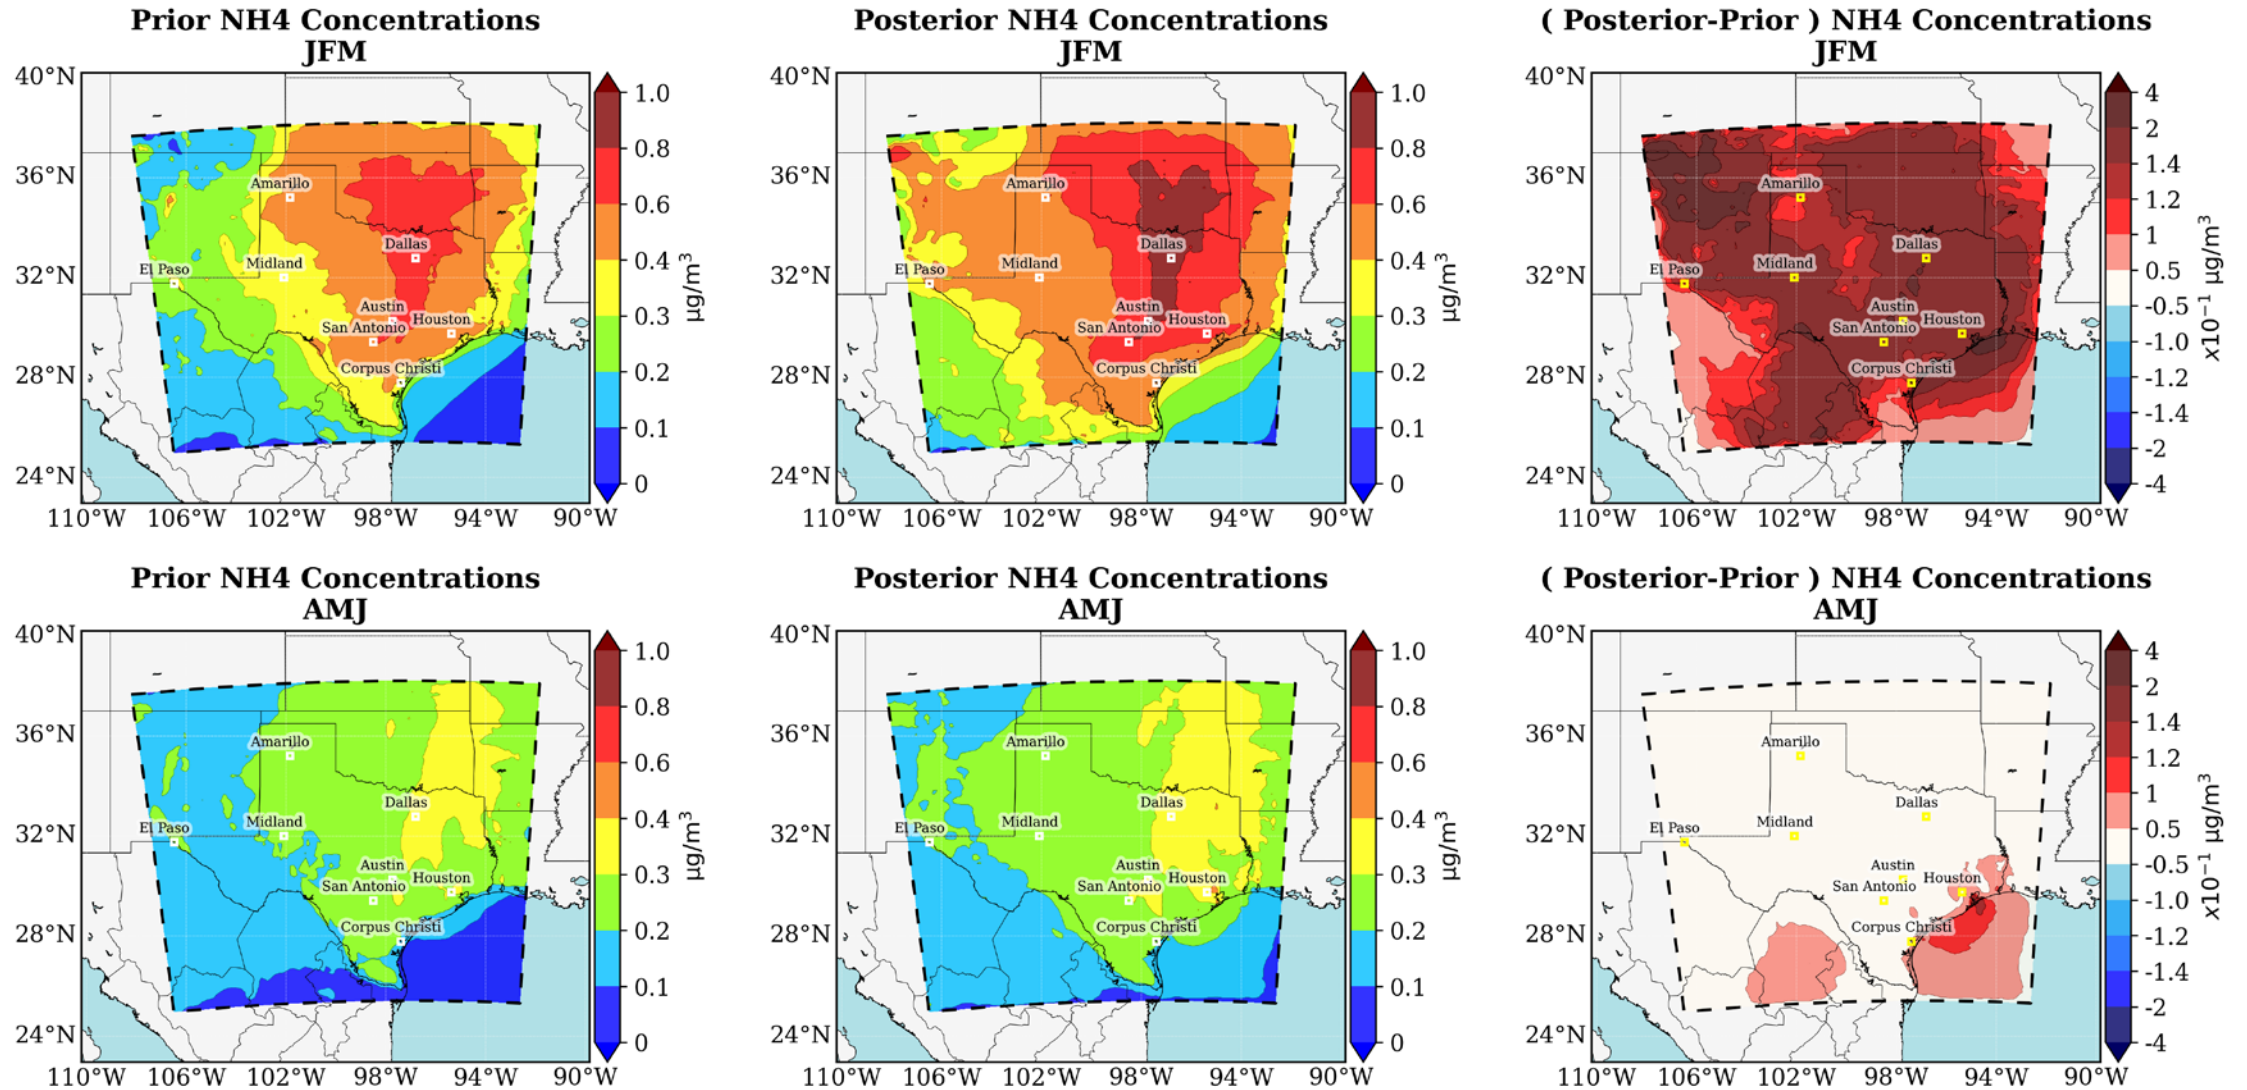

## Posterior NH<sub>3</sub> concentrations

- NH<sub>3</sub> concentrations across Texas have shown an increase.
- The most substantial increase occurred in the Northwestern regions, where values rose between 3-4 ppb.
- In the rest of Texas, including most of the northern parts and some eastern areas, the increase ranged between 1-2 ppb.
- Over the Gulf of Mexico, the 1-2 ppb increase in NH<sub>3</sub> concentrations highlights the notable role of sources over the ocean, related to biological nitrogen fixation and maritime and oil industrial activities.

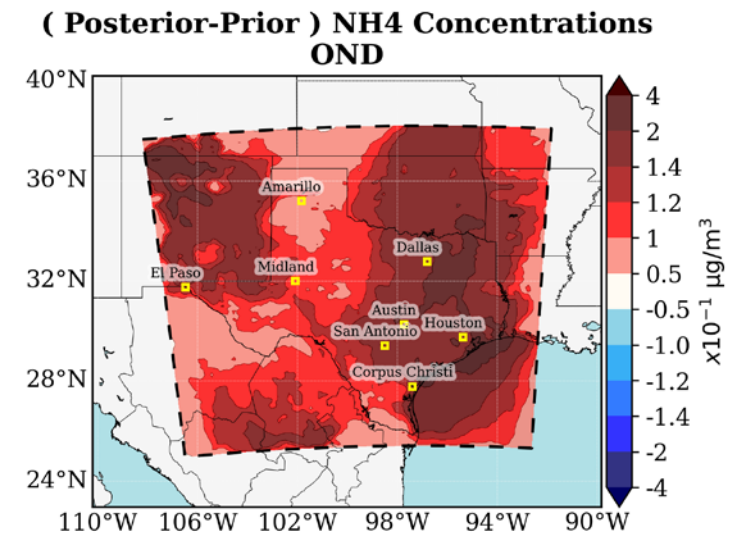

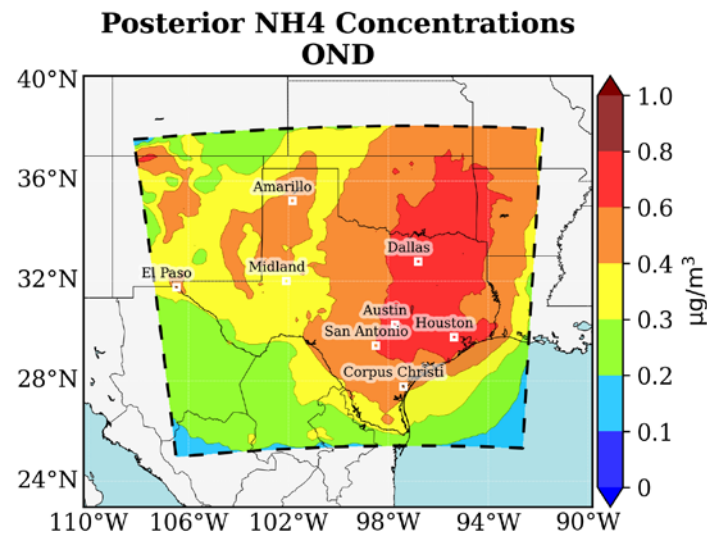

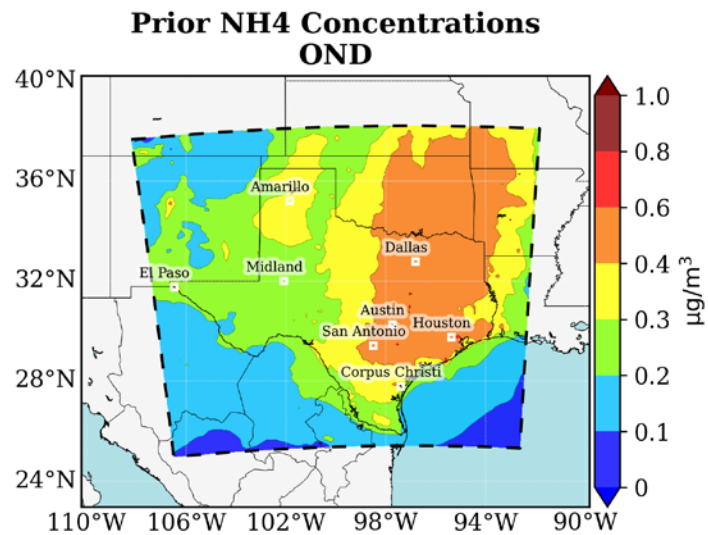

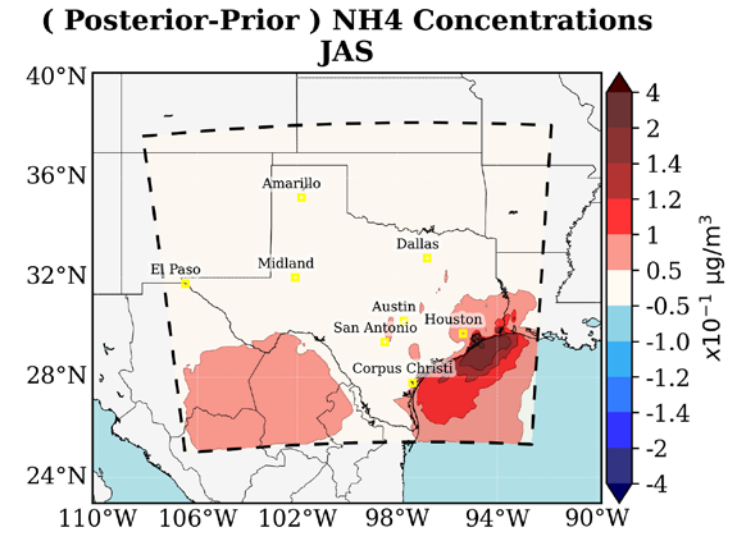

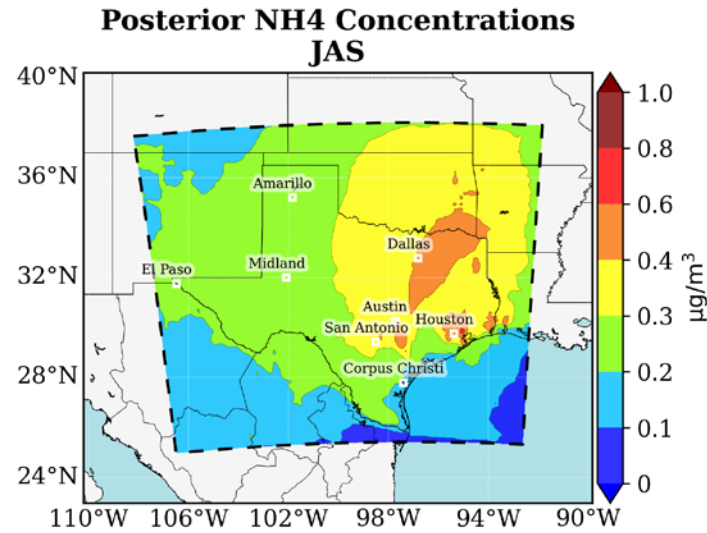

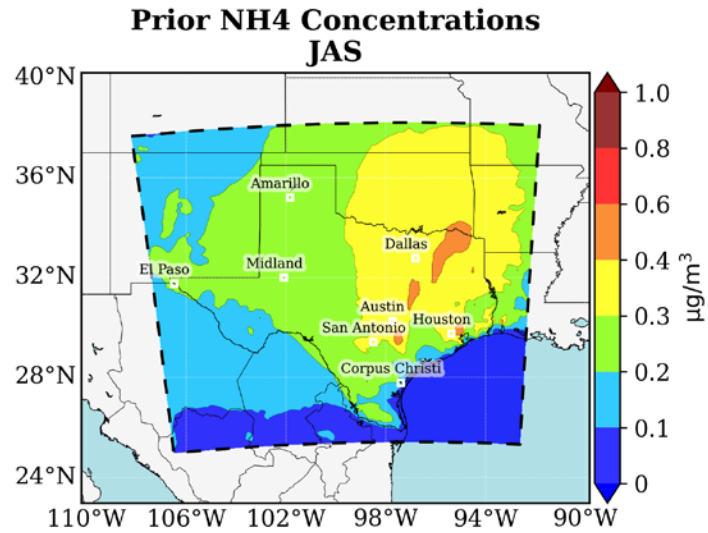

# Results

## Posterior $\text{NH}_4^+$ concentrations

# Results

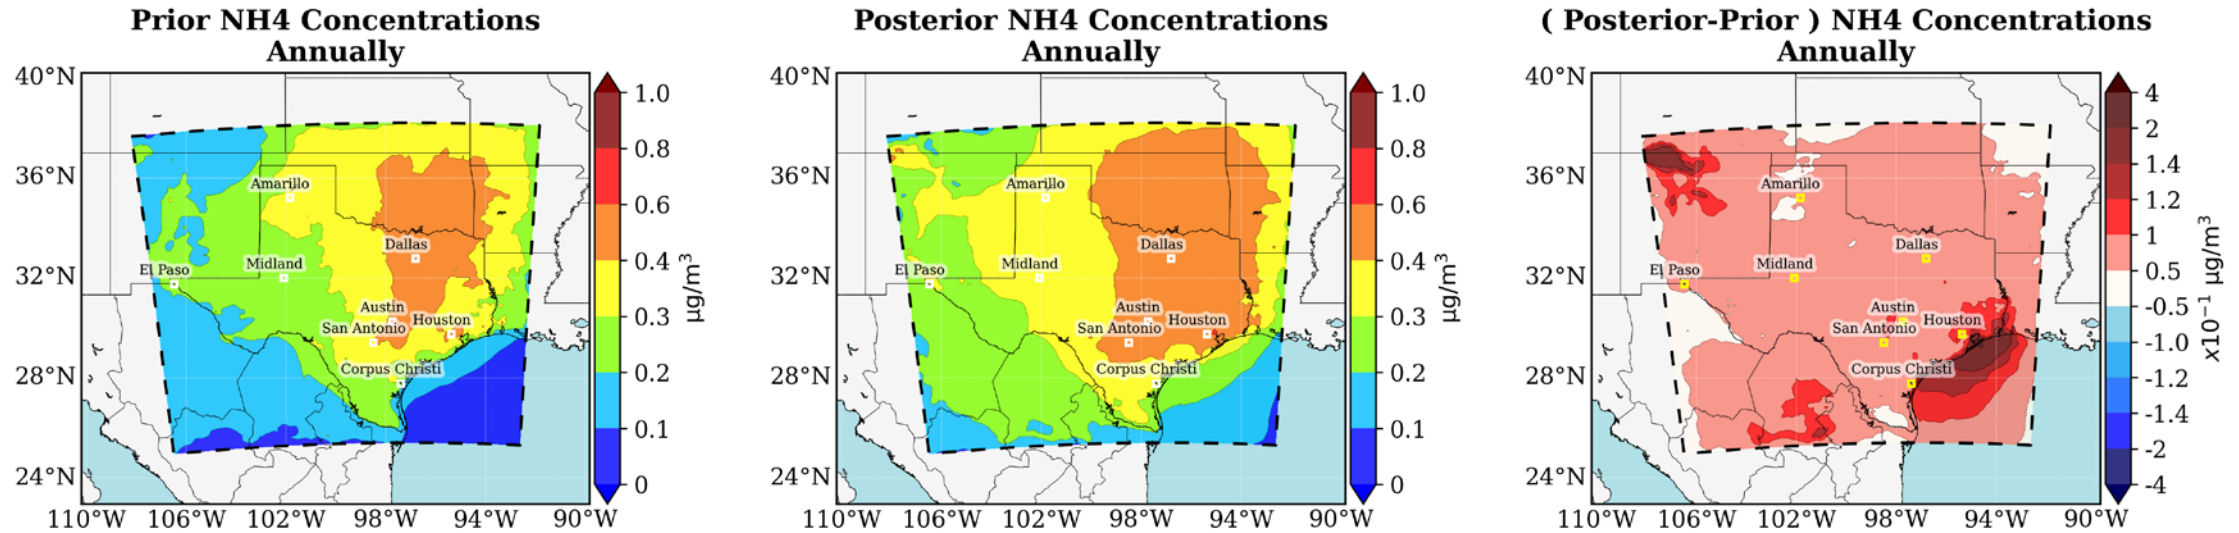

## Posterior $\text{NH}_4^+$ concentrations

# Results

26

## Posterior $\text{NH}_4^+$ concentrations

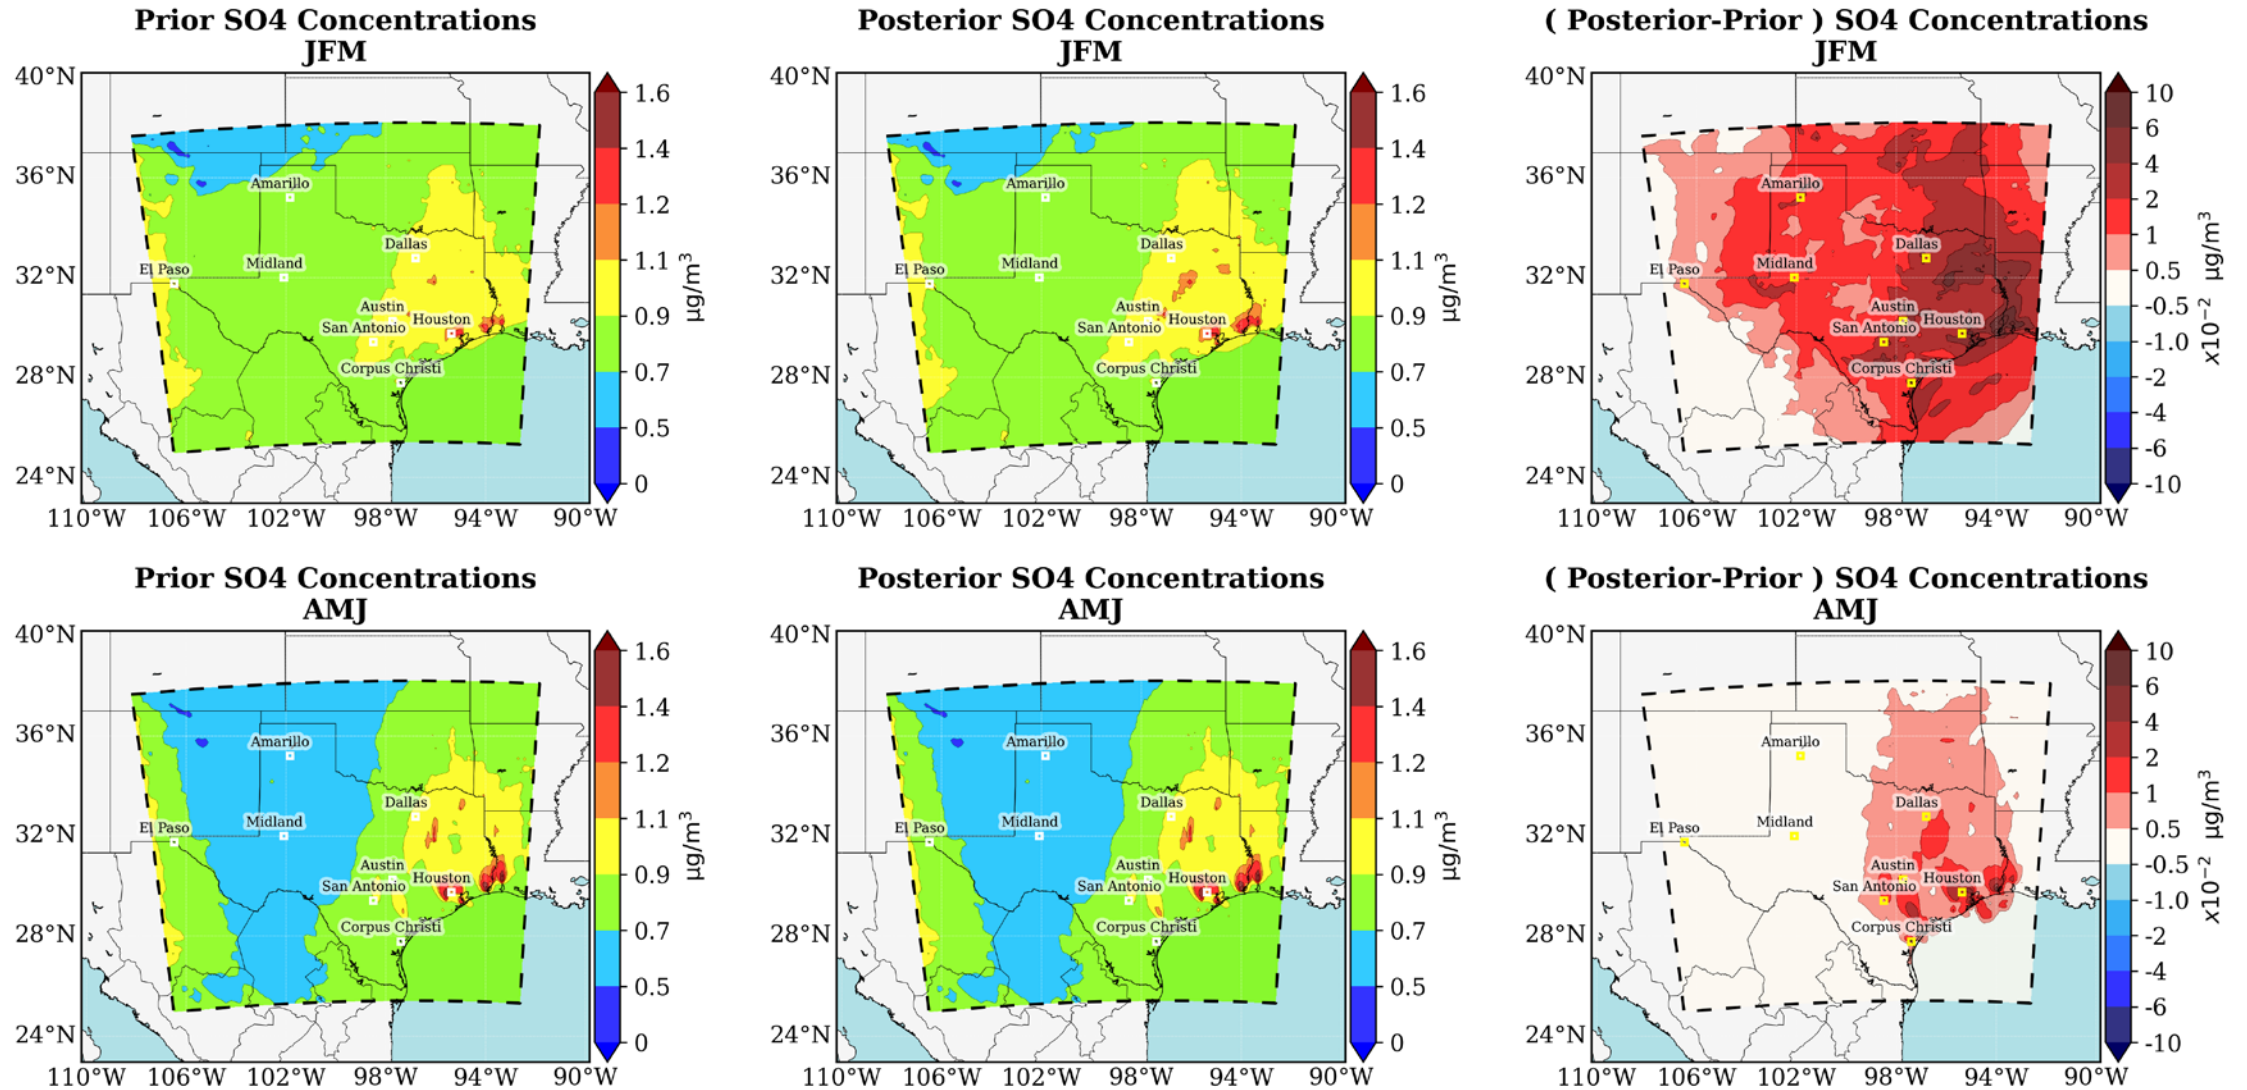

- $\text{NH}_4^+$  concentrations over Texas increased slightly, whereas values in the eastern part of the state increased more significantly.
- Over the Gulf of Mexico,  $\text{NH}_4^+$  values escalated more compared to those over Texas.
- The notable hotspot over the Gulf of Mexico, particularly in the southern parts, warrants further investigation.

# Results

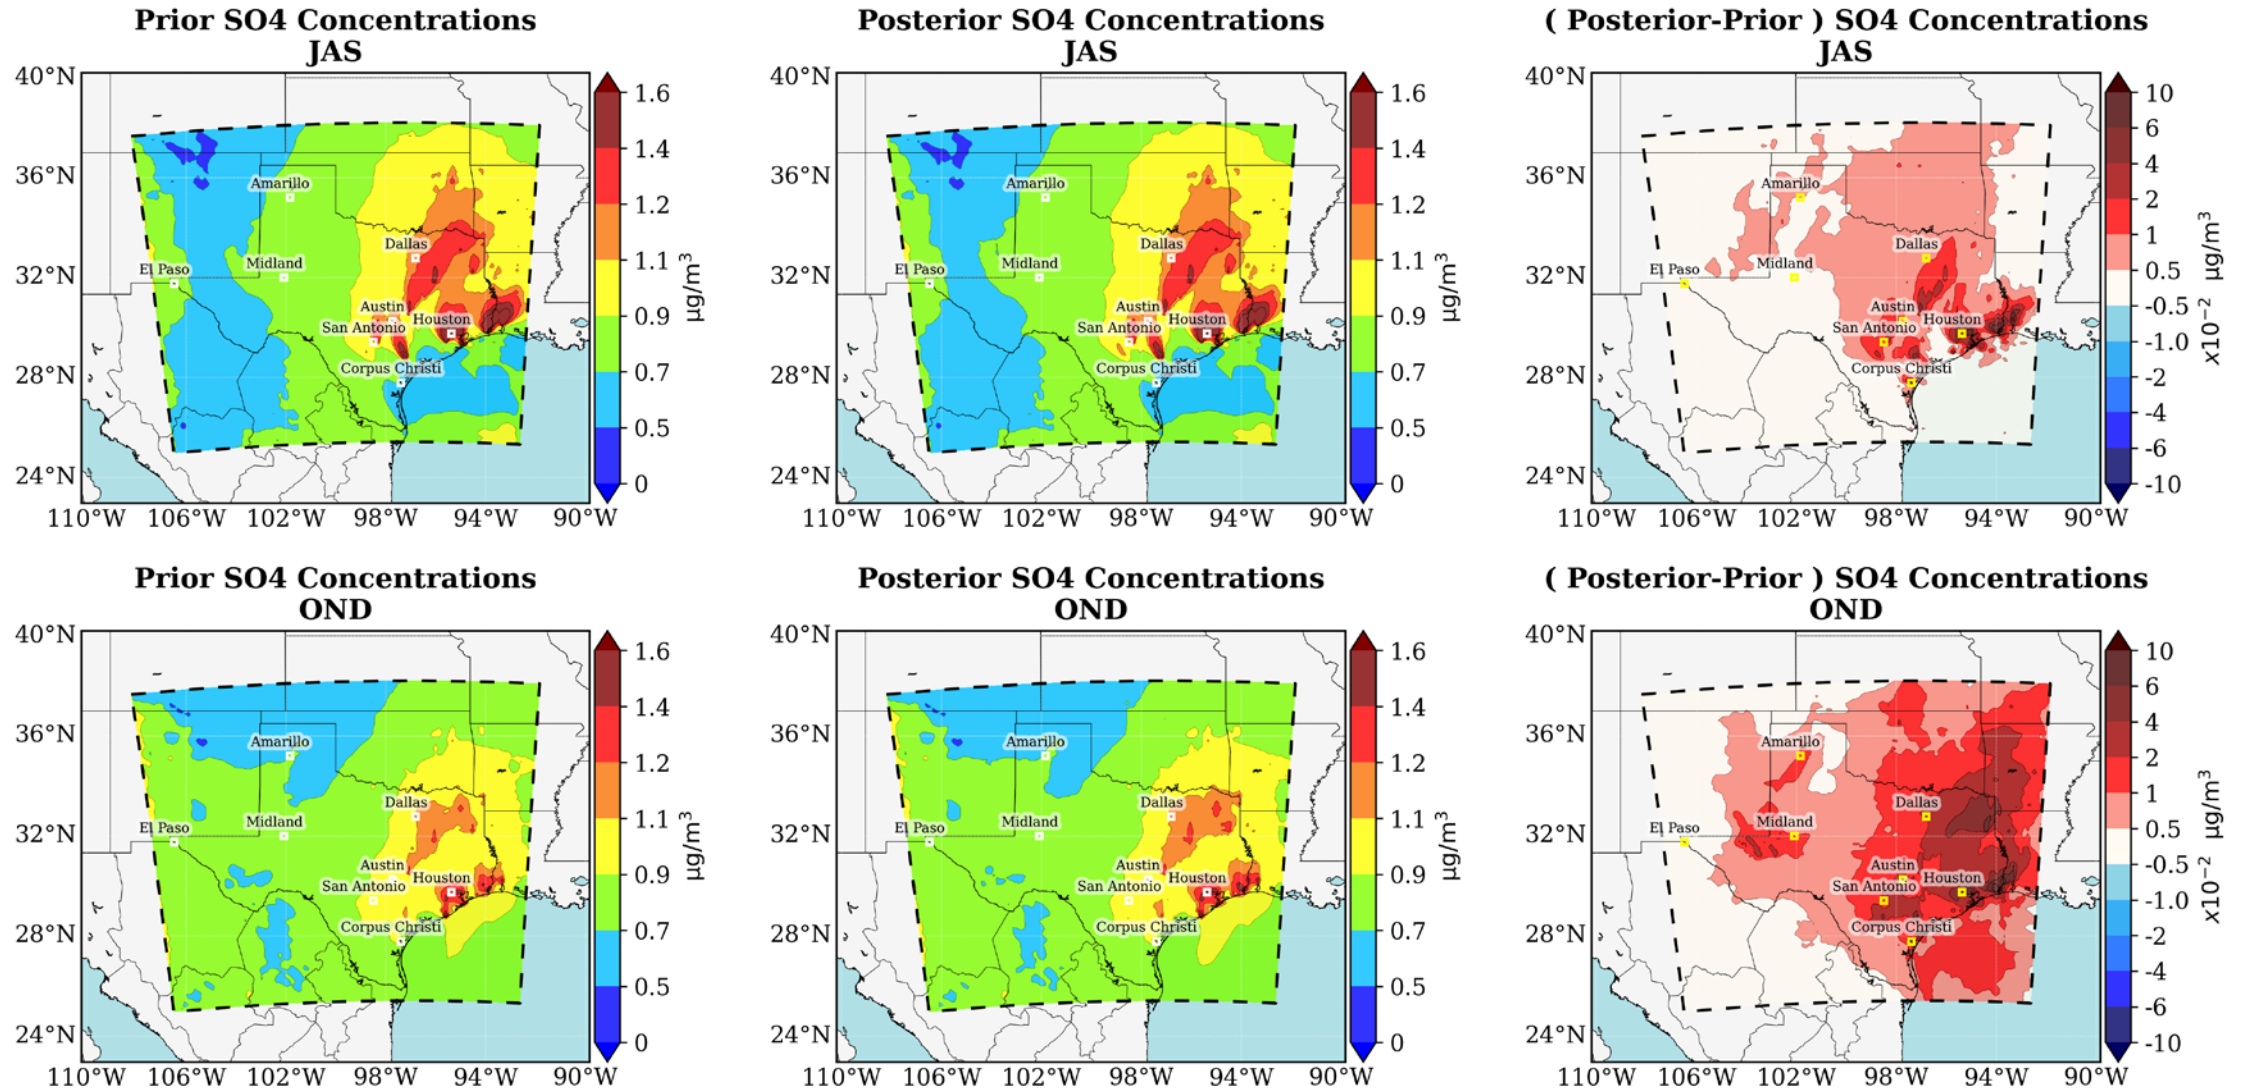

27

## Posterior $\text{SO}_4^{2-}$ concentrations

# Results

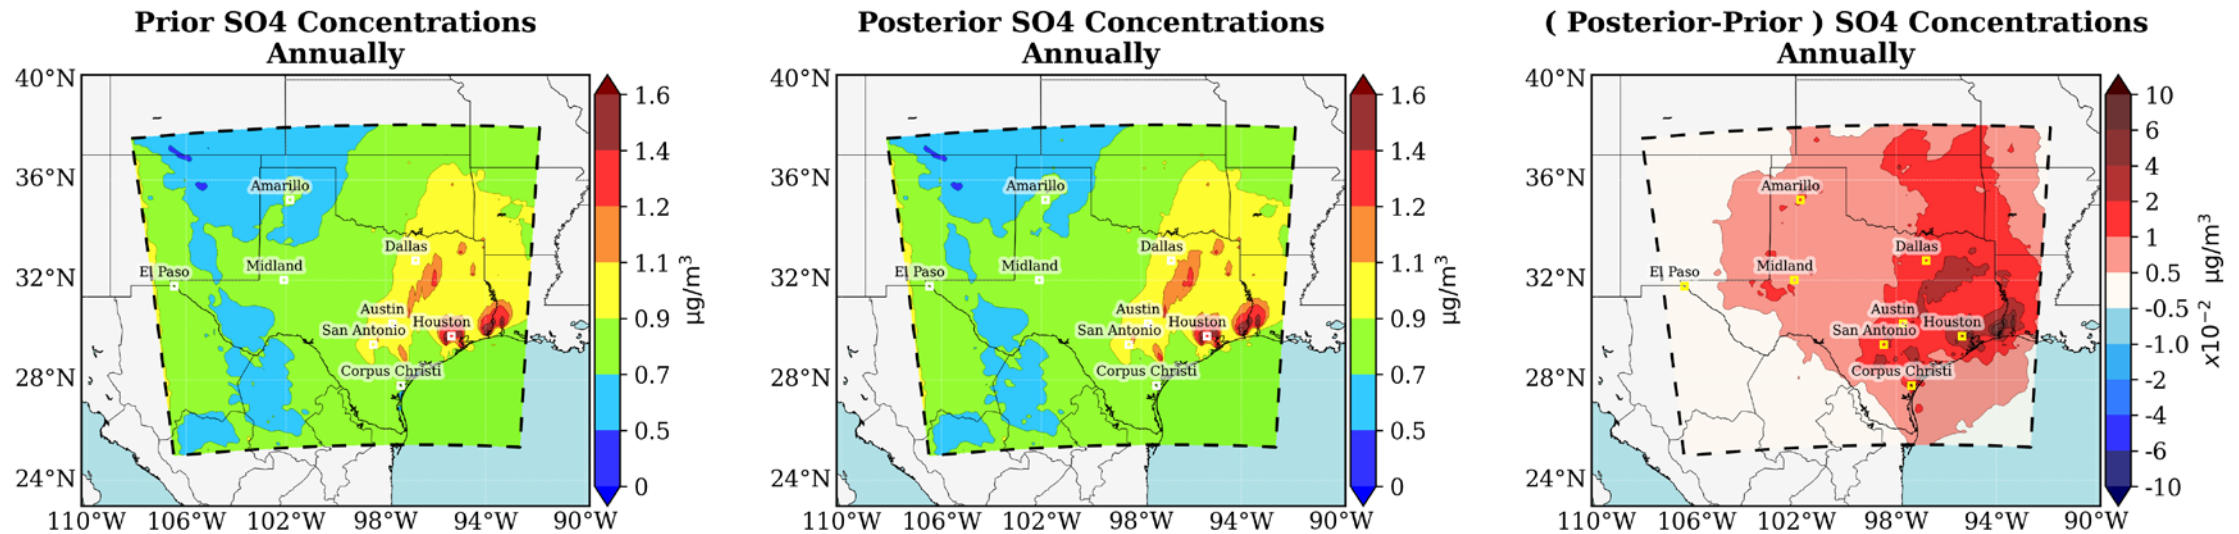

## Posterior $\text{SO}_4^{2-}$ concentrations

# Results

29

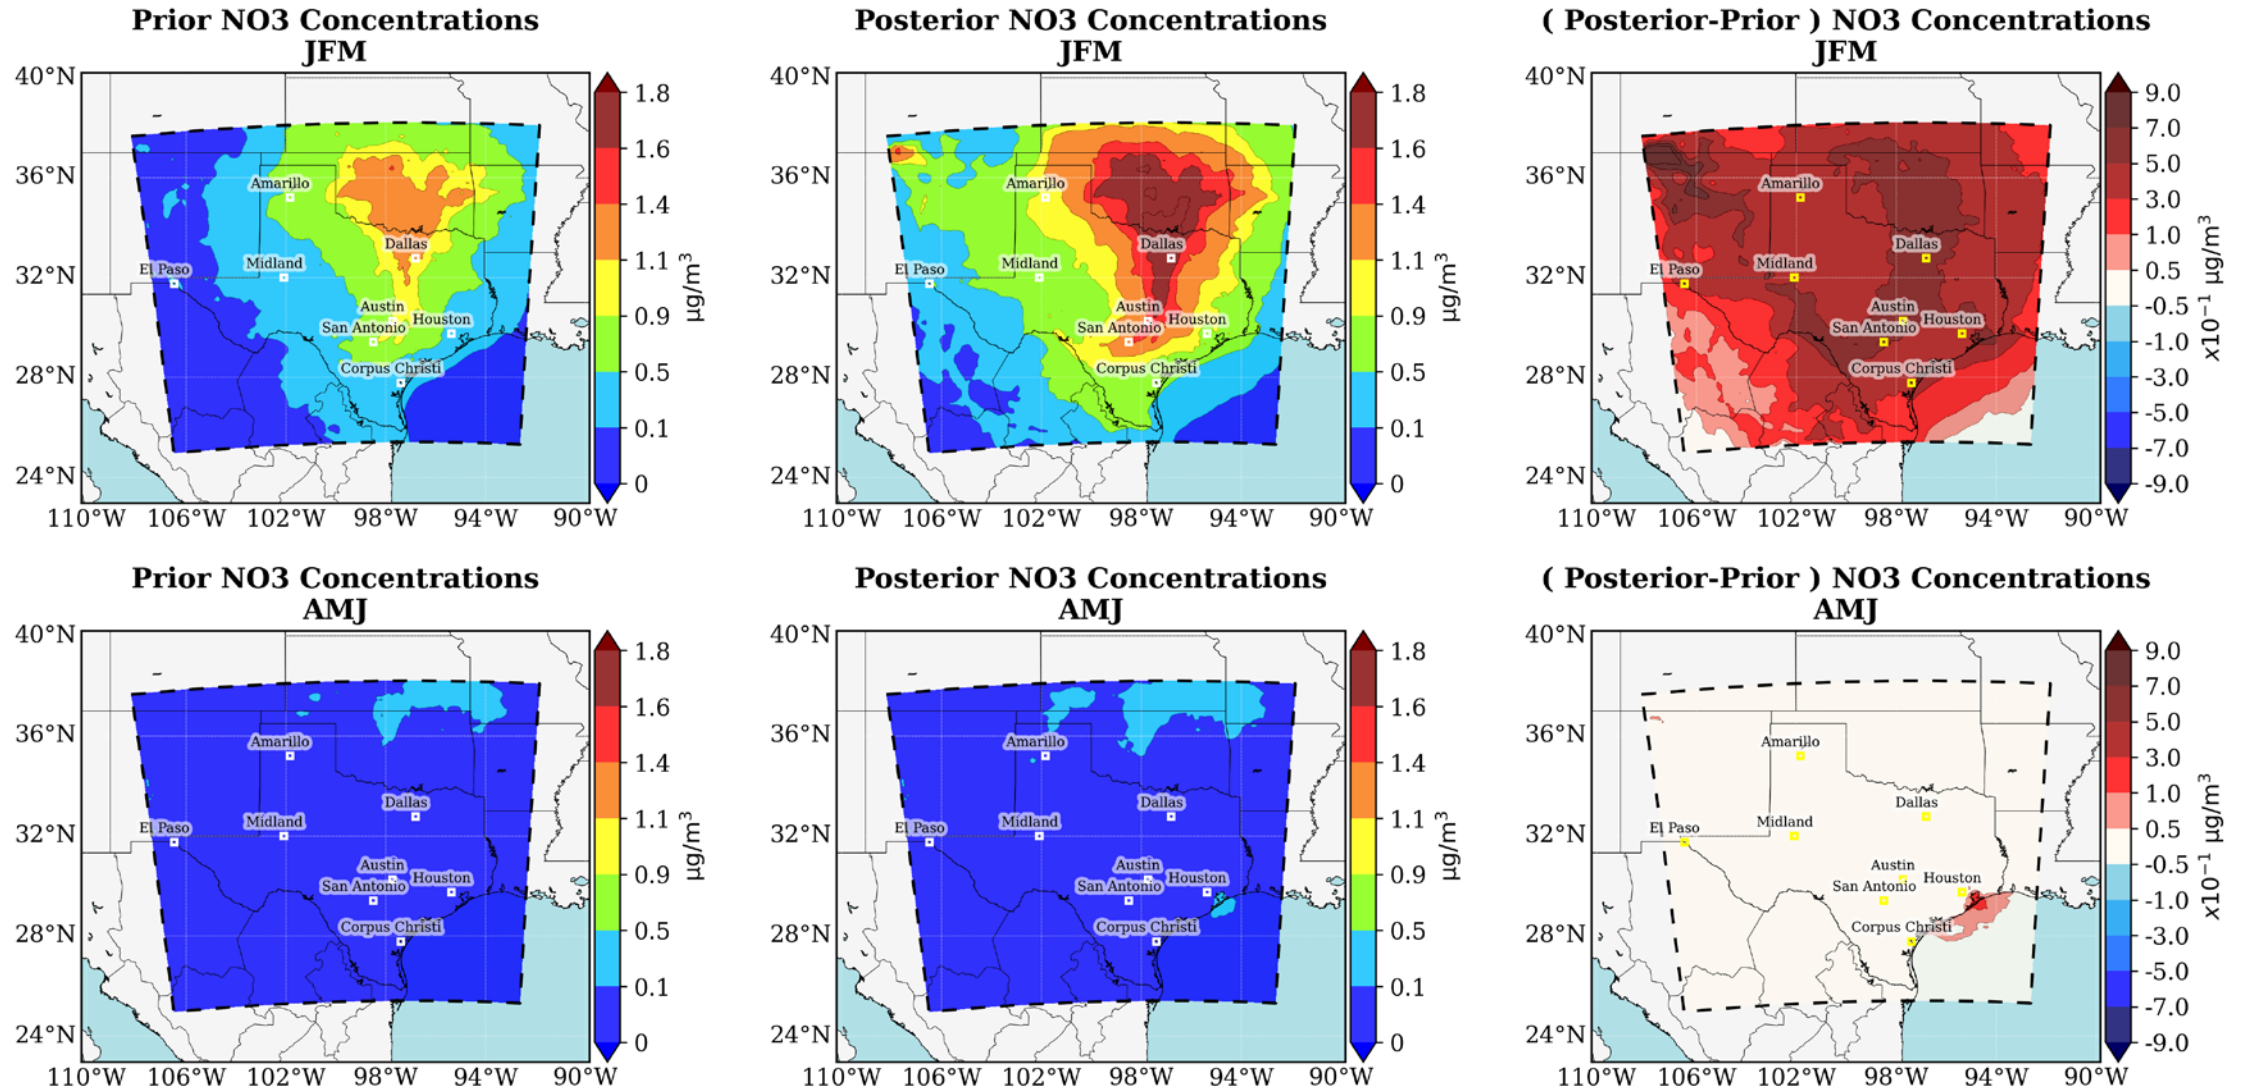

## Posterior $\text{SO}_4^{2-}$ concentrations

- A-posteriori  $\text{SO}_4^{2-}$  concentrations experienced a greater increase in eastern Texas, particularly in areas where a-prior  $\text{SO}_4^{2-}$  concentrations were already high.
- The significant increase in  $\text{SO}_4^{2-}$  concentrations near the Port Arthur and Galveston area, located in the southeast, emphasizes the potential importance of human activities, such as industrial operations and shipping, in contributing to the  $\text{SO}_4^{2-}$  emissions within this region.

# Results

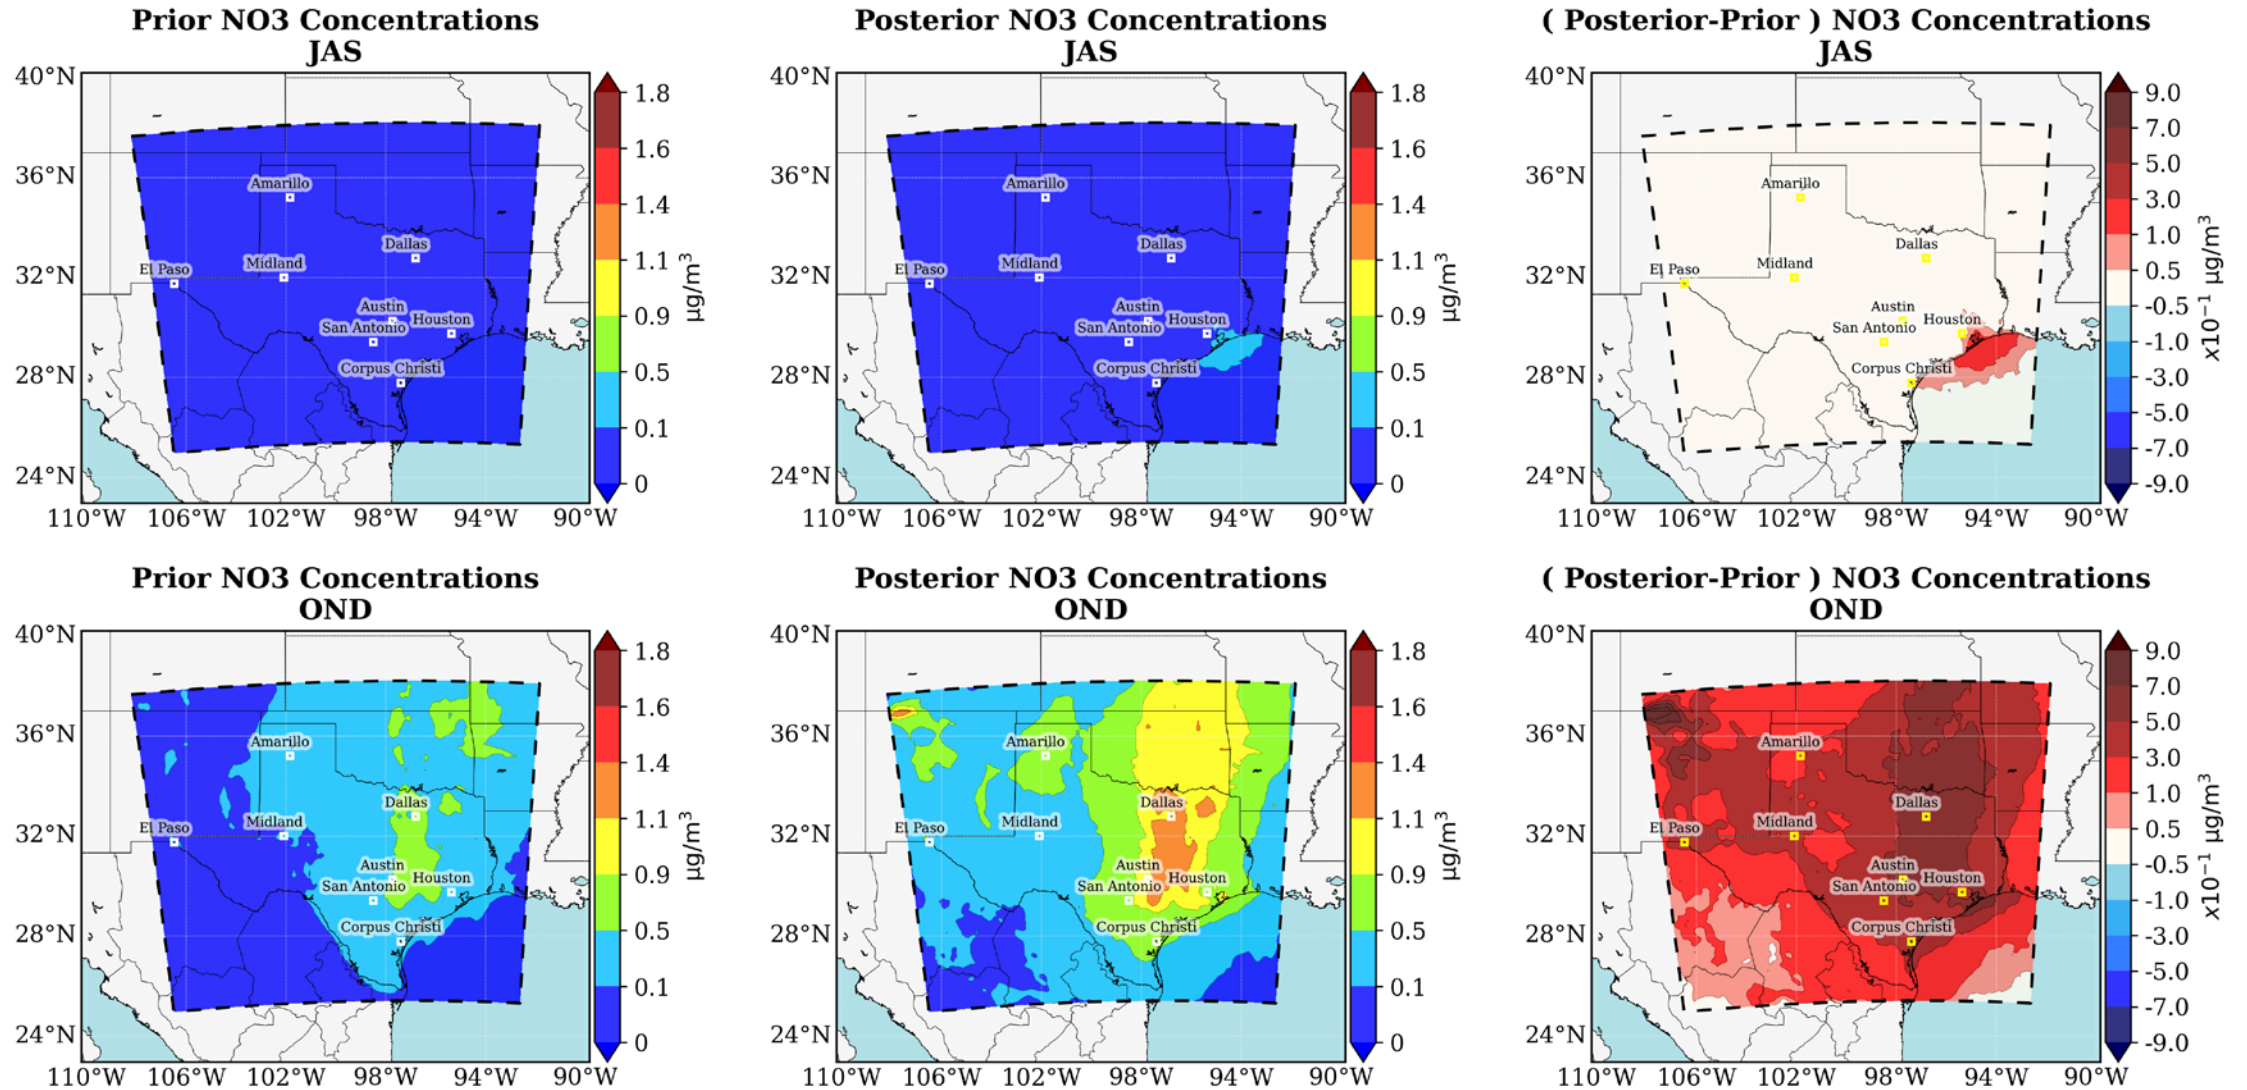

## Posterior $\text{NO}_3^-$ concentrations

# Results

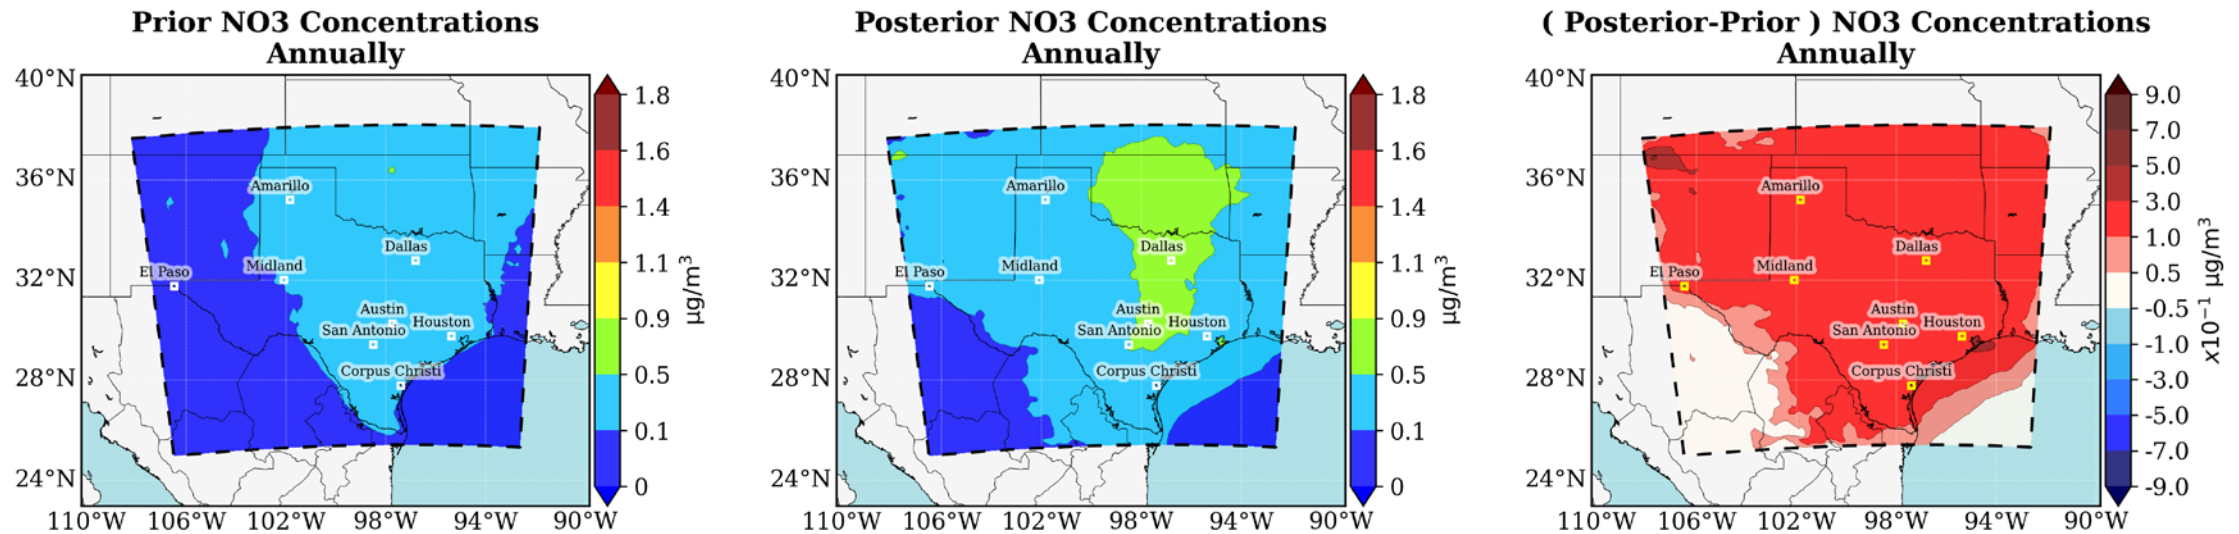

## Posterior $\text{NO}_3^-$ concentrations

# Results

32

## Posterior $\text{NO}_3^-$ concentrations

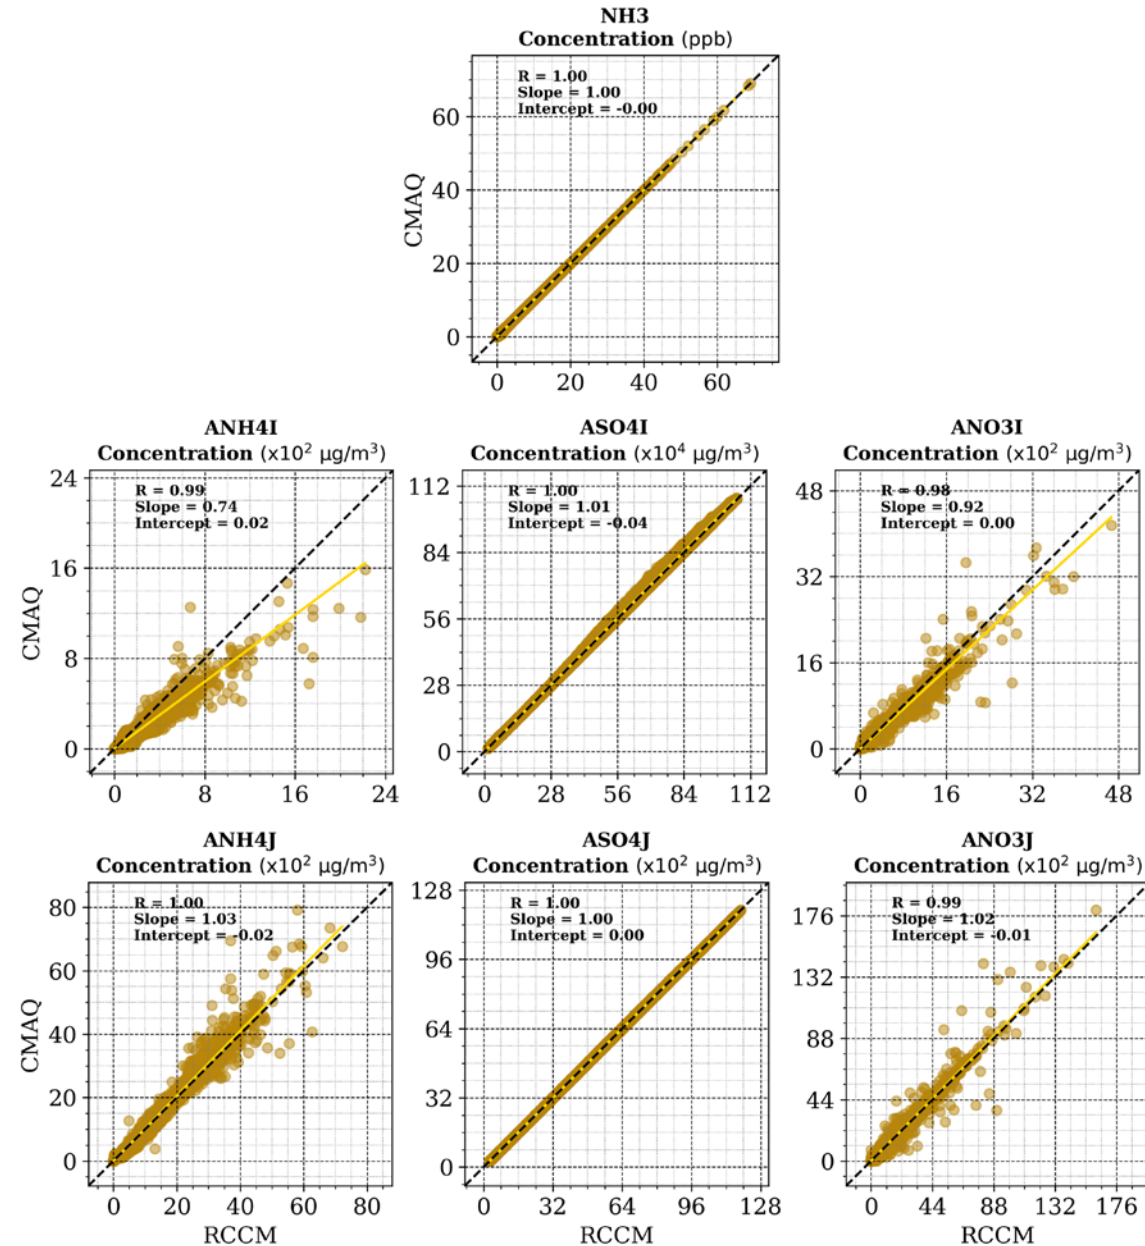

- For  $\text{NO}_3^-$ , increases were simulated throughout Texas.
- The elevated  $\text{NH}_3$  has likely resulted in an ammonia-rich regime where adequate  $\text{NH}_3$  neutralizes  $\text{SO}_4^{2-}$  to form  $\text{NO}_3^-$  production.
- The enhanced a-posteriori  $\text{NO}_3^-$  levels along the shoreline in the Gulf of Mexico are also noteworthy. This increase may be attributable to the high levels of  $\text{SO}_2$  emitting from shipping activities, further emphasizing the human influence on these emissions.

# Evaluation

33

## RCCM

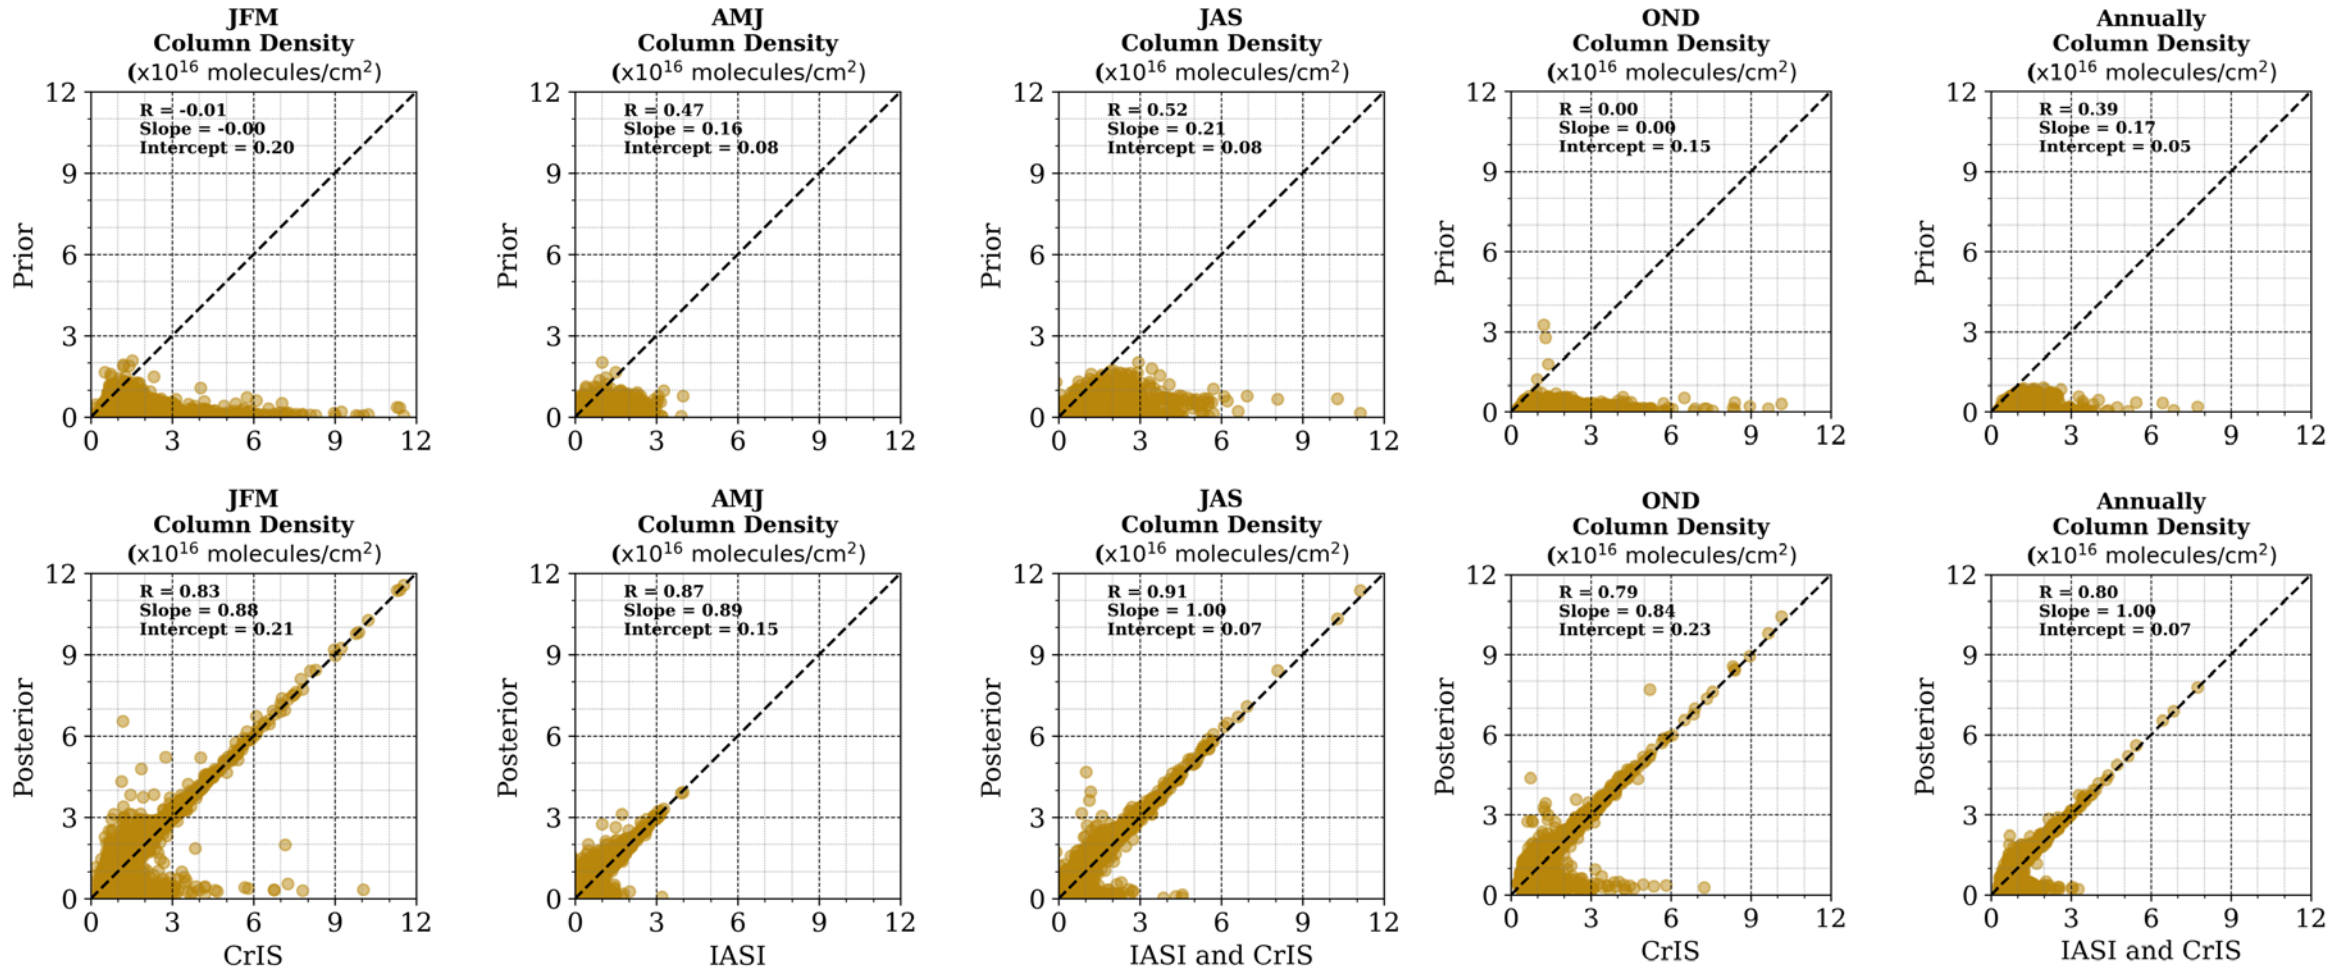

- The results illustrate that the RCCM was in closer agreement with the standard CMAQ.

# Evaluation

34

## Posterior evaluation with satellites observations

# Evaluation

35

## Posterior evaluation with satellites observations

| Quarter  |           | R      | MAE  | NMSE | RMSE | IOA  |
|----------|-----------|--------|------|------|------|------|
| JFM      | Prior     | -0.01  | 1    | 6.82 | 1.26 | 0.65 |
|          | Posterior | 0.83   | 0.27 | 0.13 | 0.45 | 0.91 |
| AMJ      | Prior     | 0.47   | 0.42 | 2.99 | 0.55 | 0.39 |
|          | Posterior | 0.87   | 0.17 | 0.15 | 0.24 | 0.92 |
| JAS      | Prior     | 0.52   | 0.59 | 2.95 | 0.80 | 0.48 |
|          | Posterior | 0.91   | 0.19 | 0.10 | 0.28 | 0.95 |
| OND      | Prior     | 0.0002 | 0.88 | 6.95 | 1.04 | 0.67 |
|          | Posterior | 0.79   | 0.23 | 0.12 | 0.36 | 0.89 |
| Annually | Prior     | 0.39   | 0.70 | 3.32 | 0.77 | 0.39 |
|          | Posterior | 0.80   | 0.20 | 0.09 | 0.28 | 0.89 |

- The posterior model performs substantially better than the prior model across all quarters and on an annual basis in terms of all the measured metrics.

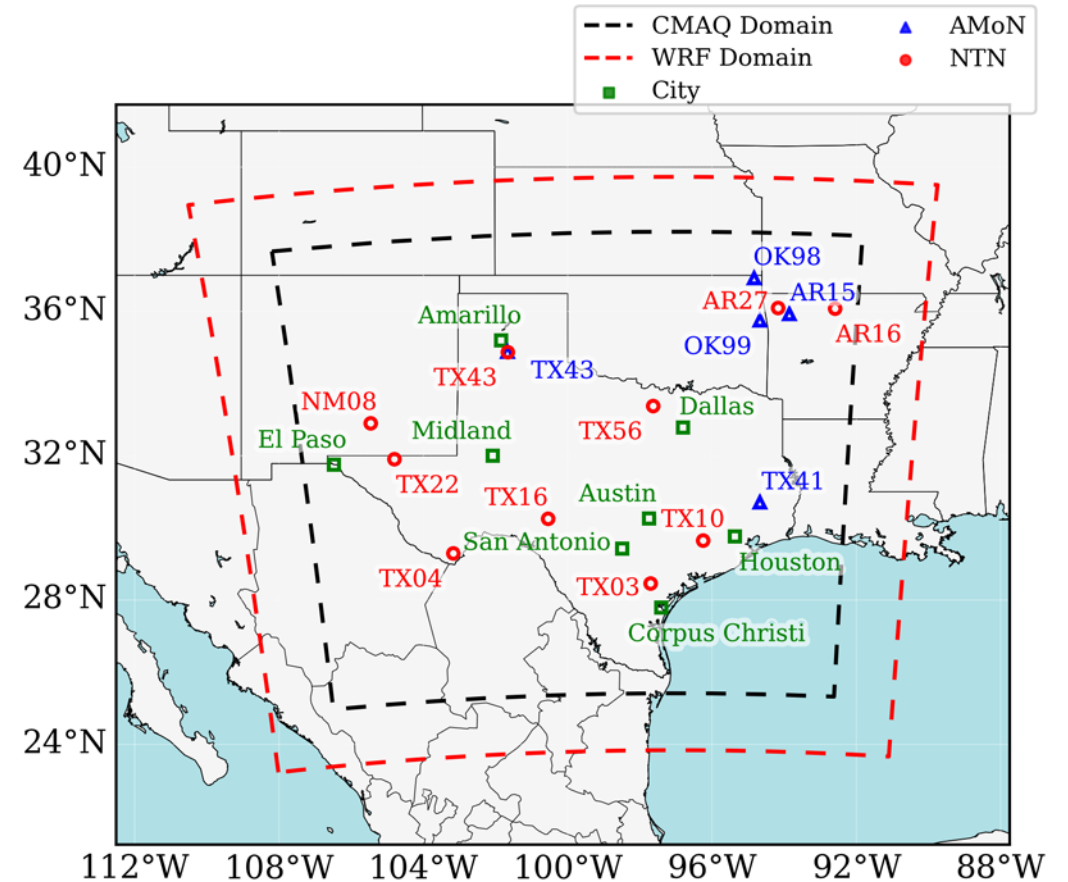

# Evaluation

36

## Posterior evaluation with surface measurements

The location of stations

- AMoN:  $\text{NH}_3$  surface concentration
- NTN:  $\text{NH}_4^+$  wet deposition measurement

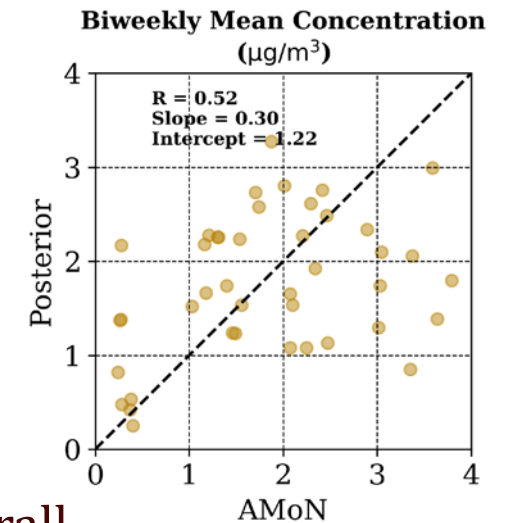

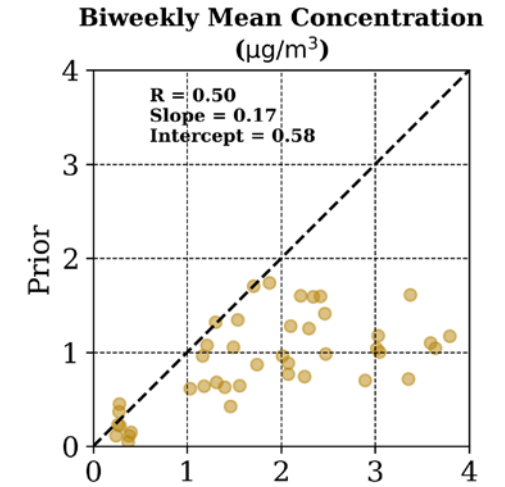

# Evaluation

37

## Posterior evaluation with surface measurements

|           | R    | MAE  | NMSE | RMSE | IOA  |
|-----------|------|------|------|------|------|
| Prior     | 0.50 | 1.17 | 1.46 | 1.67 | 0.54 |
| Posterior | 0.52 | 0.92 | 0.38 | 1.20 | 0.67 |

- The table shows that the updated (posterior) NH<sub>3</sub> emissions provide an overall improved performance over the prior NH<sub>3</sub> emissions, offering more accurate predictions and a better fit with observed values.

# Evaluation

## Posterior evaluation with surface measurements

|           | MAE  | NMSE | RMSE | IOA  |
|-----------|------|------|------|------|
| Prior     | 0.28 | 2.58 | 0.34 | 0.40 |
| Posterior | 0.26 | 1.71 | 0.33 | 0.37 |

- The posterior result seems to have improved the MAE, NMSE, and RMSE values, but the IOA has decreased slightly.

# Conclusion

39

- The results showed a noticeable increase in ammonia emission levels is observed over Texas.
- The coastline and extending over the Gulf of Mexico, demonstrates significantly elevated emission levels in comparison to the a-priori emissions.
- The updated emissions derived through our inverse modeling suggest the necessity of a thorough reevaluation of ammonia emissions from the Gulf of Mexico.
- For  $\text{NH}_3$  concentrations, the most substantial increase occurred in the Northwestern regions, where values rose between 3-4 ppb, while in the rest of Texas, including most of the northern parts and some eastern areas, the increase ranged between 1-2 ppb.
- For  $\text{NH}_4^+$  concentrations, the notable hotspot over the Gulf of Mexico, particularly in the southern parts, warrants further investigation.
- For  $\text{SO}_4^{2-}$  concentrations, the significant increase in near the Port Arthur and Galveston area emphasizes the potential importance of human activities.
- For  $\text{NO}_3^-$  concentrations, increases were simulated throughout Texas.
- The posterior evaluation showed that iFDMB is able to improve  $\text{NH}_3$  emissions with the reasonable efficiency and performance with the less run time.

**Thank you!**
